

# Quantifying the Detection of Directly Perceived Flicker

**Andrew Bierman**

Lighting Research Center, Rensselaer Polytechnic Institute

ENERGY STAR® Lighting Webinar Series  
*February 25, 2016*

# What is flicker?

- ◆ Rapid fluctuation of light output over time
  - › Unintentional result from operating on 50/60 Hz line power
  - › Can be intentional to control light output
    - For example, pulse width modulation (PWM)

# Different reasons to be concerned about flicker

## ◆ Health

- › Seizures
- › Headaches, stress, general malaise

## ◆ Safety

- › Identifying moving machinery
- › Location confusion (phantom arrays)

## ◆ Productivity

- › Visual task performance (e.g. legibility)

## ◆ Perception

- › Comfort/annoyance
- › Lighting Quality

This presentation concerns the human perception of flickering light. Perception is not necessarily related to health, safety and productivity.

For example

- Fluorescent lamp flicker at 100 Hz is not perceptible, yet it is implicated in causing headaches
- Flickering candlelight is generally regarded as safe, but it is obviously perceptible.

# Two flicker regimes

- ◆ Flicker can be perceived in two ways:
  - **Direct** perception of light fluctuation
    - Frequencies  $< 100$  Hz
    - No motion involved
  - **Indirect** perception of stroboscopic effects (phantom array, wagon-wheel effect)
    - Typically frequencies  $> 100$  Hz
    - Relies on movement of the eye or stimulus
- ◆ This presentation is about **directly perceived** flicker

# Measuring the light waveform

- ◆ The first step in characterizing flicker perception is **accurately** capturing the light waveform

Must resolve amplitude variations  $< 0.5\%$

# Measuring Direct Flicker

- ◆ The goal of this study was to develop a method and test procedure for quantifying detection of direct flicker.
- ◆ Characteristics of flicker that influence perception include:
  - Frequency
  - Waveform shape (including: modulation depth, duty cycle, rise/fall time, etc.)

Included as variables in this study

---

Typical office/home conditions employed

- Light level
- Stimulus size (visual solid angle) and retinal image location (central fovea vs periphery)
- Spectral composition (color); for white light sources there might be a slight influence that is not accounted for by photopic weighting

# Approach

- 1) Express the light waveform as a series of sinusoidal components of different frequencies (Fourier series)
- 2) Determine the perceptual strength of each sine wave in the series
- 3) Combine the individual perceptual strengths to determine the overall effect.

## Step 1 Waveform components

# Step 2

- ◆ Determine the sensitivity to sinusoidal modulation as a function of frequency. Modulation threshold is the modulation (% flicker) needed for a 50% flicker observation rate.

LRC study results for the sensitivity to sinusoidal flicker

# Step 3

- The combined perceptual effect of different frequency components appears to follow rules of Euclidean vector addition (Euclidean distance).

$$Result = \sqrt[n]{\sum_k (M_{P_k})^n}$$

$n=2$

Component 1  
(e.g. 20 Hz)

Component 2 (e.g. 40 Hz)

Other ways of combining:

“Manhattan taxicab” distance ( $n = 1$ )

Arithmetic addition shown by this and other studies as wrong.

“Chess board” or Chebyshev distance ( $n = \infty$ )

Result = longest vector. Appears in earlier literature (De Lange, 1961).

Perz et al. (2015) found optimal fit to their data with  $n = 3.7$ , but not much different than  $n = 2$ .

# Experiment verifying Euclidean distance combination

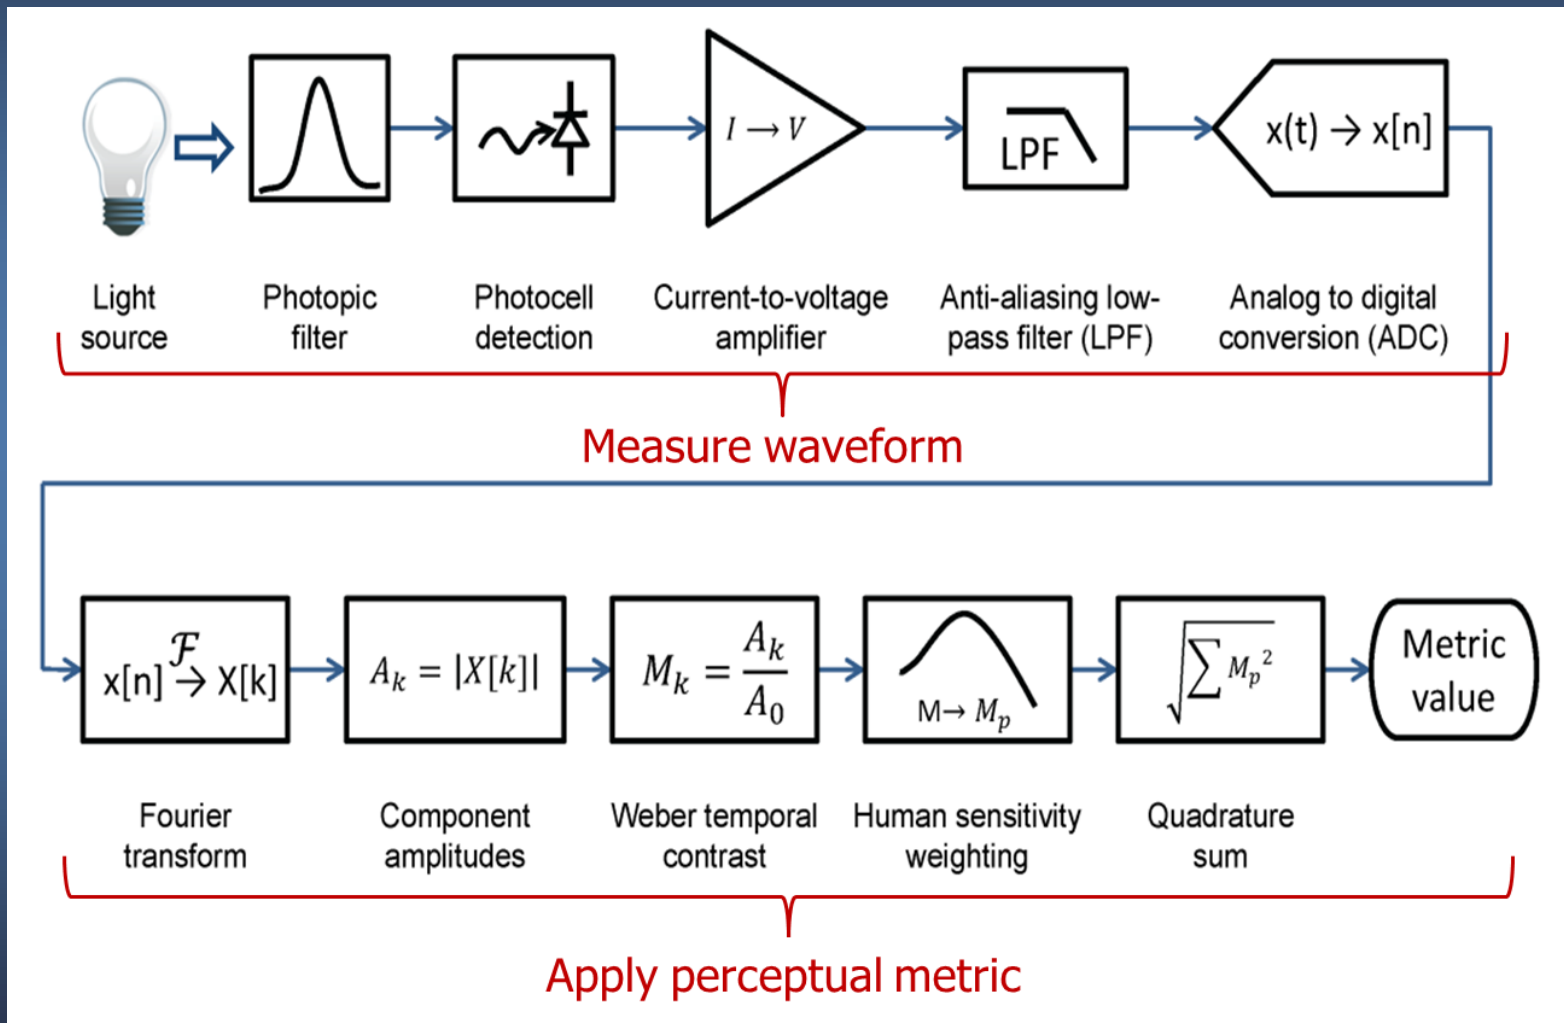

Waveform (sinusoids)	Modulation Percent by Component to Reach flicker Detection Threshold*				Metric value ( $\pm 1\sigma$ )
	10 Hz	15 Hz	20 Hz	25 Hz	
<b>15Hz + 20 Hz</b>		0.30	0.41 $\pm$ 0.03		0.97 $\pm$ 0.05
<b>15Hz + 20 Hz</b>		0.49	0.14 $\pm$ 0.05		0.94 $\pm$ 0.03
<b>20Hz + 25 Hz</b>			0.38 $\pm$ 0.09	0.24	0.84 $\pm$ 0.18
<b>20Hz + 25 Hz</b>			0.34 $\pm$ 0.06	0.36	0.87 $\pm$ 0.10
<b>10Hz + 15 Hz</b>	0.12	0.57 $\pm$ .04			1.09 $\pm$ 0.07
<b>10Hz + 15 Hz</b>	0.30	0.44 $\pm$ .14			0.95 $\pm$ 0.24
<b>10Hz + 15 Hz</b>	0.48	0.35 $\pm$ .05			0.95 $\pm$ 0.06
<b>15Hz + 25 Hz</b>		0.30		0.39 $\pm$ 0.07	0.84 $\pm$ 0.10
<b>10Hz + 25 Hz</b>	0.24			0.57 $\pm$ 0.05	1.01 $\pm$ 0.08
<b>10 Hz + 15Hz + 25 Hz</b>	0.18	0.18		0.54 $\pm$ 0.05	0.98 $\pm$ 0.07
* $\pm$ values indicate components that were adjusted by subject, the other components were fixed.					

# Proposed ASSIST Flicker Metric (Direct Flicker)

- ◆ Collect light waveform
  - $X_n$  = sampled waveform, Sampling frequency > 1000 Hz, 0.1% amplitude resolution
- ◆ Fourier transform
  - $X_k = \sum_{n=0}^{N-1} x_n e^{-\frac{i2\pi kn}{N}}$ ,  $A_k = \frac{\sqrt{\text{Re}(X_k)^2 + \text{Im}(X_k)^2}}{N}$ ,  $k = 1, 2, 3, \dots$
- ◆ Divide by dc (Weber contrast)
  - $M_k = \frac{A_k}{A_0}$
- ◆ Weight by human threshold sensitivity
  - $M_{Pk} = \frac{M_k}{M_{DTHk}}$
- ◆ Sum independent frequency components
  - $M_P = \sqrt{\sum_k (M_{Pk})^2}$
  - $k = 1, 2, 3, \dots$

# ASSIST Flicker Metric

# Testing the Proposed Metric

- ◆ The observed rate of flicker detection matched (within experimental uncertainty) with the metric value for all waveforms tested
  - Over 200 different waveforms tested (square, rectangular, sine waves)
  - (Also tested actual LED A lamps at full power and dimmed)

Bodington, D., A. Bierman, and N. Narendran. In press. [A flicker perception metric](#). *Lighting Research and Technology*, published online ahead of print 13 April 2015.

# Interpreting metric values ( $M_P$ )

- ◆ A value of 1 is just-perceptible flicker
  - > 50% observation rate

Bodington, D., A. Bierman, and N. Narendran. In press. [A flicker perception metric](#). *Lighting Research and Technology*, published online ahead of print 13 April 2015.

# Example waveform #1

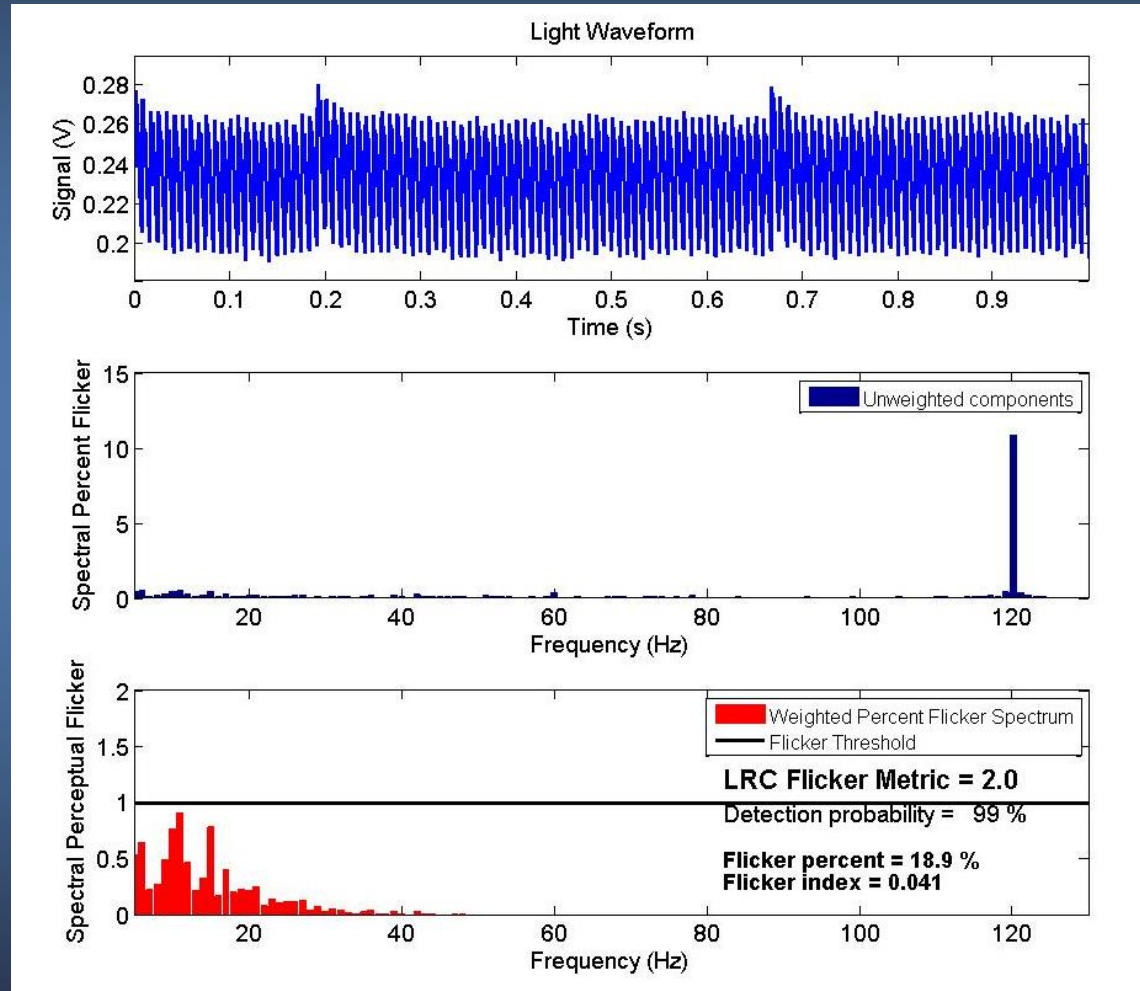

# Example waveform #2

# Example waveform #3

# An example for metric comparison

This is very **obvious flicker**: 5% duty cycle at 10 Hz  
47% flicker, Flicker Index = 0.075, ASSIST Flicker Metric = 35.4

# An example for metric comparison

This flicker is **undetectable**: 5% duty cycle at 10 Hz  
76% flicker, Flicker Index = 0.073, ASSIST Flicker Metric = 0.3

## What's the difference?

# An example for metric comparison

Low frequency ( $f < 70$  Hz) removed  
( keeping the dc component)

# An example for metric comparison

Visible flicker	47	←	Percent Flicker	→	76	No Visible flicker
	0.075	←	Flicker Index	→	0.073	
	35	←	ASSIST Metric	→	0.3	

# Thank You!
